

Proposed Method

Interest Sustainability Prediction – Predictive Model and Feature

- Given the classification problem, introduce f_i, M as shown in Fig.2.
- Intuitively, the consumption pattern of an item over time will be an important clue in determine consumed in the feature.
- To model the consumption patterns of items over time, we represent the timestamps at which an item was consumed as frequency bins:

$$\text{item} : [t_1, t_2, \dots, t_N] \xrightarrow{\text{Binning}} [b_1, b_2, \dots, b_B]$$

- t_j : j -th timestamp at which an item was consumed
- b_k : number of times an item was consumed in the period of k -th frequency bin
- N : number of consumptions of the item in D_f
- B : number of bins where $N \gg B$

Proposed Method

Interest Sustainability Prediction - Predictive Model and Feature

- To examine the benefit of the frequency bins, Fig.3 show the distribution of the frequency bins that belong to $y_i = 1$ or $y_i = 0$.
- Observe that the values in the frequency bins:
 - $y_i = 1$ tend to gradually increase over time
 - $y_i = 0$ tend to decrease in recent periods
- Therefore, use the features that capture the consumption patterns changing over time (sequence of frequency bins) to predict items will be consumed in the future.

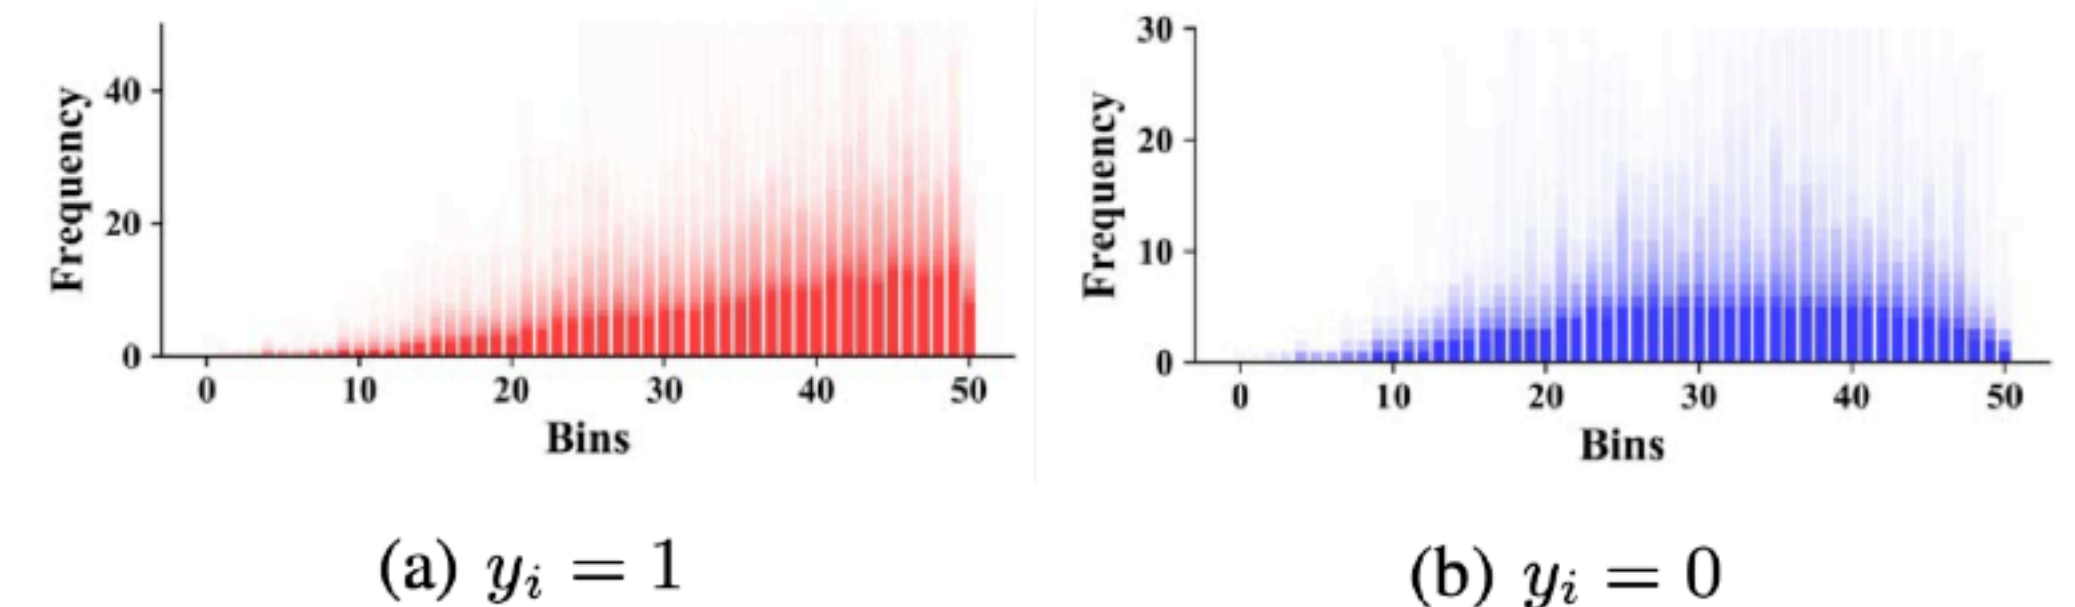

Fig. 3: Distribution of frequency bins corresponding to 10,000 randomly-sampled items that belong to $y_i = 1$ (a) or $y_i = 0$ (b) on Yelp dataset.
